

ROTORMILL

KEY FEATURES

- 8 models ranging from 15 to 750 hp
- Carbon or Stainless steel
- No special foundation required
- Adjustable air intake port
- Heavy duty construction
- Rotor assembly dynamically balanced for smooth operation
- Large doors provide easy access for replacement or adjustment of internal parts
- Grinding plates and liners can be furnished with hardened material for extended life when grinding abrasive materials

KEY BENEFITS

- Attrition milling through particle to particle collisions enhances ability to grind less friable or abrasive materials that are difficult for a fine grinder or classifier mill
- By combining several operations such as de-agglomeration and surface coating into one, a Long Gap Mill eliminates the need for multiple material handling systems
- Continuous fine milling at high production rates
- Simultaneous drying during the milling process (Rotordryer option)

Nominal

THEORY OF OPERATION

- Particles are pulverized to small sizes by inter-particle collisions induced by very high turbulence within the mill. The pulverizing action is generated by an internal rotor that spins at high speeds. Heavy-duty bearings provide stability during the pulverization process. These bearings are housed outside the grinding chamber to prevent product contamination.
- The rotor consists of two sections:

A Lower Section that functions as a material distribution fan

An Upper Section where the material is finely ground

- Grinding occurs at several stages within the upper section. A series of grinding plates accelerate the air and particles against the grooved lining of the interior of the Rotormill. Miniature pockets of high-velocity, turbulent air cause particle-to-particle collisions and pulverizes the material. Internal heat is absorbed by the continuous flow of air.
- Varying airflows, adjustable grinding plates, and specialty plate types allow for the processing of a wide variety of materials and sizes.
